

JavaScript String Datatype - Theory Notes

What is String Datatype?

A string is used to store text data in JavaScript.
Any value written inside quotes is usually a string.
Examples: Hello, 100, true, Welcome

Ways to Create Strings

1. Double Quotes -> "Hello"
2. Single Quotes -> 'Hello'
3. Backticks -> `Hello`

Special Cases

1. Empty String -> ""
2. Number in Quotes -> "100" (type is string)
3. Boolean Word in Quotes -> "true" (type is string)

Backticks Usage

Useful for multi-line strings and template literals.
Example: let name = "Ram"; `Hello \${name}`

String Object

new String("Hello") creates a String object.
Its type is object, not string.
Usually normal strings are recommended.

Important Difference

typeof "100" -> string
typeof 100 -> number
typeof "true" -> string
typeof true -> boolean

Best Practice

Use normal strings: let name = "John"
Avoid: new String("John")
